Here is the reason for this: In the original jac package in R there is a function called `jac_xyz_c(Y, x, z, logits)`. Where `logits` is passed as a matrix. We can see a similar function here: `## Linear predictor logit function(y, x, z, logits) { if (is.matrix(logits)) stop("logits must be a vector") }` lo The objective of this grant is to provide support for the training of eight postdoctoral researchers and three postdoctoral fellows, to conduct original research with colleagues at the University of Texas M.D. Anderson Cancer Center, and to provide postdoctoral trainees with a superb training environment in which to develop new directions in research. A significant effort is being made to promote and develop interdisciplinary research in cancer, which is the focus of the scientific interests of the Center. This program is based on the hypothesis that improved understanding of the normal mechanisms of cell proliferation and of cellular and molecular alterations that lead to cancer will permit the development of improved therapies. As these mechanisms become better defined, one may be able to predict or influence the response of tumor cells to specific treatments. Training will be provided in the areas of cellular and molecular biology, in experimental therapeutics, in the biochemistry of cancer biology, and in clinical oncology. In addition, an interdisciplinary team of investigators who have a track record of training in cancer biology will provide support for the development of interdisciplinary research projects. Areas in which the applicant will focus her efforts include: the basic biology of human tumor cell growth regulation, mechanisms of tumor cell resistance to therapy, and tumor-host interactions. The training program consists of five tracks in which postdoctoral trainees can participate. Postdoctoral trainees are required to have a Ph.D. and must pass examinations in clinical oncology. 82157476af
